Abstract

Objective: Brain-derived neurotrophic factor (BDNF) plays a well-established role in neuronal development and plasticity. Recently it has been speculated that BDNF may be involved in the pathogenesis of immune system diseases, because T lymphocytes can secrete BDNF and express its specific receptor tyrosine kinase B (TrkB). Our aim is to detect the serum BDNF level and the expression of TrkB on peripheral blood T cells in patients with dermatomyositis (DM) and their contribution to the disease pathogenesis.

Methods: Twenty-six patients with DM and 30 age- and sex-matched healthy controls were enrolled. The serum BDNF level was measured by enzyme-linked immunosorbent assay (ELISA). Flow cytometry was used to measure the percentage of TrkB expression on the surface of CD3+CD4+ or CD3+CD8+ T cells. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), blood lymphocyte count, platelet count, fibrinogen, D-dimer (D-D), IgG, IgM, IgA and T cell subsets were acquired from the standard laboratory procedure.

Results: Compared to the controls, the serum BDNF level of patients with DM was significantly decreased (16012.8±6012.5 pg/ml vs. 33116.5±7146.5 pg/ml, p=0.001). In addition, the serum BDNF level was significantly lower in the DM patients with interstitial lung disease (ILD) than in those without ILD (14586.6±5120.5 pg/ml vs. 20455.1±6484.5 pg/ml, p=0.028). Compared to the controls, the percentage of TrkB expression on CD3+CD4+ and CD3+CD8+ T cells was increased significantly (1.85%±1.81% vs. 0.65%±0.36%, p=0.008; 6.8%±5.27% vs. 3.0%±2.74%, p=0.007, respectively). There was no significant difference in the expression of TrkB on CD3+CD4+ or CD3+CD8+ T cells between DM patients with and without ILD.

Conclusion: The serum BDNF level and TrkB expression on T cells may reflect the disease activity of DM and could be used as serological markers of DM. Especially, a serious decline in serum BDNF level may imply a pulmonary involvement of DM.

Introduction

Dermatomyositis (DM) is an autoimmune disease of unknown etiology and poor prognosis, characterized by involved striated muscle, inflammatory cell infiltration, muscle fiber degeneration and necrosis, as well as multiple skin lesions [1,2]. Chronic proximal and pharyngeal muscle weakness are the clinical features of DM, and DM is frequently complicated with interstitial lung disease (ILD), which is one of the main causes of death. Muscle biopsy in DM patients shows necrosis, as well as multiple skin lesions [1,2]. Brain-derived neurotrophic factor (BDNF) is one of the representative members of the neurotrophin family, which plays an important role in the survival, differentiation and function of the neurons [5,6]. Previously, BDNF was considered to be existed only in the central nervous system and synthesized by astrocytes. In recent years, it has been found that the lymphocytes can also synthesize and secrete BDNF [7], and express its specific receptor: tyrosine kinase B (TrkB) [8,9]. Both BDNF secretion and TrkB expression are increased in activated T and B cells [7]. The combination of BDNF and TrkB can promote proliferation of T cells and affect the differentiation of T cells into Th1 and Th2 [10], and is involved in the maturation, proliferation and activation of B cells [11-13]. In BDNF-deficient mice, the total

Values are mean (SD), LY, lymphocyte; PLT, platelet; ILD, interstitial lung disease. **: p<0.01, compared to HC, Student’s t test.

Blood samples were divided into two parts: one was centrifuged shortly after clot formation to obtain serum, and were frozen at -80°C within 2 hours to assay the BDNF level within one month; the other was anticoagulated to obtain peripheral blood mononuclear cells (PBMC).

Measurement of serum BDNF level by ELISA

The serum BDNF level were measured by ELISA kits according to the manufacturer’s instructions (R&D Systems, Minneapolis, MN, USA). All assays were performed in duplicate. The data were presented as pg/ml.

Detection of TrkB on the surface of T cells by flow cytometry

Blood specimens were disposed with the use of lymphocyte separation medium (Ficoll-Paque™ PLUS, Amersham Biosciences) and then centrifuged to get PBMCs. The PBMCs were stained with fluorochrome-conjugated mAbs by a 30min incubation at 4°C. Stained samples were acquired by using FACSCan and Cell Quest software (BD Biosciences). The results were analyzed by FlowJo v10 software (Tree Star, Ashland, OR, USA). The expression of TrkB were calculated after gating on CD3+CD4+ or CD3+CD8+ lymphocytes. The antibodies used for the surface staining were as follows: PE-conjugated CD3 antibody (clone HIT3a; BD Biosciences); FITC-conjugated CD4 antibody (clone RPA-T4; BD Biosciences); PE-Cy7-conjugated CD8 antibody (clone RPA-T8; BD Biosciences); APC-conjugated TrkB antibody (Mouse IgG1 Clone; R&D Systems) and their Isotype controls.

Statistical analysis

Data were presented as means ± standard deviation (SD). Student’s t test, One-way analysis of variance (ANOVA) and multiple comparison (Tukey’s test) were used to examine the differences between the controls and the DM patients with ILD or without it. Pearson regression was used to examine the correlation between various laboratory measures and BDNF level. Analysis was performed with the SPSS 17.0 software. Statistical tests with two-tailed p values less than 0.05 were considered significant.

Results

Clinical characteristics of DM patients

Demographic and partial clinical profile of DM patients and healthy controls were summarized in Table 1. From the given data, 61.5% DM patients complicated with ILD. DM patients had a
significant decrease in lymphocyte count compared with the controls (1.1±0.6 vs. 2.1±0.4, p<0.001, Student’s t test).

Serum BDNF level in DM patients and healthy controls

The serum BDNF level in DM patients showed a significantly lower level compared with the healthy controls (16012.8±6012.5 pg/ml vs. 33116.5±7146.5 pg/ml, p<0.001, Student’s t test).

TrkB expression on CD3+CD4+ and CD3+CD8+ T cells in DM patients and healthy controls

Flow cytometry analysis showed that the percentage of TrkB expression on the CD3+CD4+ and CD3+CD8+ T cells (described as CD3+CD4+TrkB+/CD3+CD4+, CD3+CD8+TrkB+/CD3+CD8+) was increased significantly when compared to the controls. Figure 2 showed an example of fluorescence activated cell sorter (FACS) dot-plots for CD3-CD4, CD3-CD8, CD3CD4TrkB-SSC, CD3CD8TrkB-SSC, respectively.

Statistical analysis revealed a significant increase of the percentage of CD3+CD4+TrkB+ and CD3+CD8+TrkB+ T cells in DM patients compared to healthy controls (1.85%±1.81% vs. 0.65%±0.36%, p=0.008; 3.0%±2.74% vs. 6.8%±5.27%, p=0.007 respectively, Student’s t test) (Figure 3(a) and (b)).

Association between the serum BDNF level, TrkB expression and laboratory data

Table 2 presents the results of Pearson regression between laboratory data and serum BDNF level or percentage of TrkB on T cell subsets. The serum BDNF level in DM patients was negatively correlated with D-D, positively correlated with lymphocyte and PLT count. The percentage of CD3+CD8+TrkB+ T cells was negatively correlated with Fib.

vascular endothelial cells [34,35], and can enhance vascular flow and plays an important role in vascular development and survival of capillaries and arteries also secret BDNF and express TrkB. BDNF DM is often accompanied by lymphopenia [33]. Our data did show a marked low BDNF level might be associated with a certain role in immune system diseases, supporting the neuron-immune network theory [29]. Lymphocyte is one of the main sources of serum inflammatory cells and reduces the extension of immune response in autoimmune diseases.

It has been well established that BDNF has potential therapeutic value for some central nervous system degenerative diseases, such as Alzheimer’s, Parkinson’s and Huntington’s diseases [26-28]. Recently, accumulating evidence indicates that neurotrophins play a certain role in immune system diseases, supporting the neuron-immune network theory [29]. Lymphocyte is one of the main sources of BDNF in peripheral blood. TrkB is the specific receptor of BDNF. The binding of BDNF and TrkB can promote the differentiation of T cells into TH1 and TH2, and play an important role in the proliferation and survival of T cells, as well as have anti T cell apoptotic effect [30-32]. Previous studies have suggested that the low BDNF level attenuates the proliferation and differentiation of inflammatory cells and reduces the extension of immune response in autoimmune diseases.

In this study, we found that the serum BDNF level was decreased in DM patients. We speculated that this may be attributable to three factors. Firstly, lymphocyte is one of the main sources of serum BDNF, thus, the low BDNF level might be associated with a marked decrease of lymphocyte count in DM patients. It is well known that DM is often accompanied by lymphopenia [33]. Our data did show a positive correlation between the BDNF level and lymphocyte count.

Secondly, endothelial cells and vascular smooth cells of capillaries and arteries also secret BDNF and express TrkB. BDNF plays an important role in vascular development and survival of vascular endothelial cells [34,35], and can enhance vascular flow and regulate revascularization of ischemic tissues [36]. DM patients often have impaired endothelial function and inflammation of vascular wall, manifested as skin vacuities, vascular lesions of muscle and pulmonary vacuities. As one of the sources of BDNF, endothelial impairment may also contribute to the decrease of serum BDNF level in DM patients. Moreover, D-D is a sensitive marker of vascular wall damage and acute thrombosis. The more severe of the endothelial cells are damaged, the higher the concentration of D-D is. Our results showed that BDNF and D-D were negatively correlated, suggesting that low BDNF might be significant in judging the damage of vascular wall. Consistent with this, previous reports also found a decrease in the serum BDNF level in systemic sclerosis patients, which has been related to microvascular disease and impaired endothelial function in systemic sclerosis [16].

Thirdly, muscle biopsy of DM patients indicates that there are amount of CD4+ T cells infiltrating in the skin rash, muscle tissue and lung [3]. Thus, there is a possibility that a large amount of BDNF accumulates in tissues of DM patients and then is consumed locally. This is required to be further examined using pathological and immunohistochemical methods.

Our results showed that the serum BDNF level of DM patients combined with ILD was the lowest. Endothelial function of DM patients with ILD were more seriously impaired, and muscle biopsy of DM patients indicates that there were amount of CD4+ T cells infiltrating in the lung [3]. In addition, Immunoblots revealed that fibroblastic foci in idiopathic pulmonary fibrosis (IPF)/usual interstitial pneumonitis (UIP) strongly was stained for BDNF and TrkB [37-39]. Lung tissue may be the target of CD3+CD4+TrkB+ cells infiltration in DM patients. Those above supported our result that the serum BDNF level of DM with ILD was lower.

It has been reported that the BDNF level in platelet-poor plasma was lower. Platelets may have a non-releasable pool of BDNF or the released BDNF binds to a recognition site on the platelet surface and is internalized. Thrombin and collagen can induce a rapidly amount of release of BDNF from platelets. Our result that the BDNF level was positively correlated with PLT count was accordant with the report above. In contrary, the specific BDNF receptor, TrkB, was not detected in platelets. No BDNF mRNA was detected by Northern blotting in platelets [40].

Until now we do not know the reason of the increase of TrkB expression on T cell surface in DM patients. Though TrkB expression could be up-regulated in response to the decrease of BDNF level, our data does not show a clear negative correlation between serum BDNF level and percentage of TrkB. This issue is worthy of further investigation to reveal the signal transduction pathways initiated by the binding of BDNF to TrkB, and the interaction between BDNF and other inflammatory factors.

In summary, the present findings provide the first evidence for a role of BDNF level as a marker of disease activity and poor prognosis in DM, especially for the DM which is complicated with ILD. This study raise the possibility, which should be investigated by further studies with larger patient cohorts, that by measuring BDNF at the time of diagnosis we might obtain more information about the disease and the risk of ILD accompanied.

The serum BDNF level and interstitial lung disease

The serum BDNF level in DM patients with ILD was significantly lower than that in the patients without ILD (14586.6±5120.5 pg/ml, n = 16) vs. 20455.1±6484.5 pg/ml, n=10, p=0.028 (Figure 4). There was no significant difference in TrkB expression on CD3+CD4+ or CD3+CD8+ T cells between DM with and without ILD (1.81%±1.95% vs. 1.93%±1.58%, p=0.886 ; 6.49%±5.12% vs. 7.60%±6.04%, p=0.674 respectively).

**Discussion**

In this study, we, for the first time, examined the serum BDNF level and TrkB expression on T cells in DM patients. We found that the serum BDNF level in DM patients was significantly lower than that in healthy controls, while the TrkB expression on the CD3+CD4+ and CD3+CD8+ T cells in peripheral blood was significantly higher. It has been well established that BDNF has potential therapeutic value for some central nervous system degenerative diseases, such as Alzheimer’s, Parkinson’s and Huntington’s diseases [26-28]. Recently, accumulating evidence indicates that neurotrophins play a certain role in immune system diseases, supporting the neuron-immune network theory [29].
