#### Abstract

Major fractions of the proteome of Leptospira are hypothetical proteins, necessitates their identification and characterisation to disclose their role in the pathogenesis. The presented *in-silico* characterisation approach analyzed the Leptospiral protein (LA\_1016); in terms of physicochemical parameters, family relationships, motif and fold details, subcellular localisation nature and interaction networks. And annotated the hypothetical protein as an extracellular protein, containing a coiled-coil motif and an immunoglobulin-like fold. At the same time no domain, family or functional evidence could be identified with confidence. Virulent factor analysis, toxin prediction, antigen prediction and secondary structure identification were also carried out. And the protein was predicted as exotoxin and as an antigen. The revealed secondary structure proportions were; 21.19%, 10.80%, 28.12%, and 39.89% respectively for alpha helix, beta turn, extended strand and random coil. In addition, the epitope analysis explored the potential linear B-cell epitopes of the protein. The possibility of these antigenic epitopes as potential candidates for the peptide driven diagnostic and vaccine strategies can be considered. Besides, the revealed extracellular localisation nature points to the importance of the protein as a valuable diagnostic target with the potential of early diagnosis of Leptospirosis. Thus, the study gives the possibility of LA\_1016 as a potential diagnostic target and vaccine candidate having implication in the pathogenesis of Leptospirosis.

# Introduction

Leptospires are corkscrew-shaped bacteria responsible for an emerging zoonotic infectious disease Leptospirosis [1]. Only a few portions of Leptospiral proteins are reviewed, besides the data regarding their full characterisation and their role in the biology of Leptospira is lacking. In the case of Leptospira interrogans serovar Lai, only approximately 11.5% of total proteins are reviewed. Currently, most of the total proteins are assigned as hypothetical proteins, which are proteins whose existence has been predicted through conceptual translation from the open reading frames but there is no experimental data validating their existence [2]. The hypothetical proteins constitute major fractions of the proteome of prokaryotes [3]. Thus, identification and characterisation of these proteins may lead to the invention of new functions, interacting cascades and their contribution to the proteome of an organism [4].

*In-silico* characterisation of hypothetical proteins is an indispensable tool which may help in the identification of new proteins and also for designing and focusing experiments on unknown proteins. There are so many publicly available prediction servers aimed for the *in-silico* prediction of protein characters such as physicochemical parameters, subcellular localisation, protein family, domain and fold identification, toxic property prediction, antigen detection, and homology modelling. Among the *in-silico* characterisation approaches, protein similarity searches are one of the

first steps for the identification of unknown proteins. Can be employed through sequence alignment and homology detection by servers such as BLASTp and protBLAST [5]. Which enable the comparison of the query sequence with the database through sequence alignment and identify library sequences that match the query sequence?

Protein sequence information and physicochemical properties can be identified using Prot Param server. Proteins secreted through the classical protein secretory pathway are depend on a signal peptide, which is a stretch of 16-30 amino acid sequences at the amino terminus of the protein [6]. The signal peptide sequence and cleavage site can be identified through SignalP software which is based on a combination of several artificial neural networks. Some proteins are secreted through a signal peptide-independent, nonclassical secretory pathway. However, their mechanism of secretion is unknown; the SecretomeP software enables the prediction of these classes of secreted proteins [7]. TMHMM, HMMTOP, and CCTOP are topology prediction tools enable the identification of the transmembrane helices presence within the protein sequences, which is a characteristic of membrane spanning proteins [8-10]. Protein subcellular localisation prediction is one strategy to infer the functions of unknown proteins. Prediction tools such as Cello, Psortb, PSL pred, SoSuiGramN, and MetaLocGramN are specialized for the prediction of protein subcellular localisation from amino acid sequences.

Motif and domain identification of unknown proteins can infer about the functions of proteins. Protein family relationships can be employed through Pfam database search, which is a collection of protein families [11]. SUPERFAMILY annotations are based on hidden Markov model domain search at the superfamily level [12]. Coiled-coils are structural motif having biological implications. Expasys' COILS server calculates the probability of coiled-coil conformation within a protein sequence. The fold recognition software's uses amino acid sequences to identify proteins belong to a fold; evolutionary distant but structurally similar proteins [13]. Prediction server like PFP-FunD SeqE identifies the fold pattern of proteins, which are the pattern of polypeptide chains in space [14]. Inter Pro protein functional characterisation depends on domain and repeats based family classification and sequence analysis [15]. And STRING database allows identification of functional and physical interactions of proteins from the predicted and known interactions. Table 3: The subcellular localisation analysis.

Prediction server aiming identification of virulent proteins and toxic property of hypothetical proteins are valuable tools. Toxin prediction servers like BTX pred predicts the possibility of a toxic peptide from the amino acid or dipeptide composition. VICM pred and MP3 servers are designed for the functional characterisation of the proteins as virulent molecules. Reverse vaccinology is an important approach in vaccine research, depends on the prediction of protective antigens with the benefit of whole genome sequence data. VaxiJen is such an alignment independent bioinformatics prediction tool, prediction of a proteins' potential as vaccine candidate is based on the physicochemical properties [16].

# **Materials and Methods**

## Sequence, similarity identification

The sequence information the hypothetical protein (LA\_1016) identified through MALDI-MS analysis (previous data) was collected from the NCBI database [17]. The sequence data was submitted to several prediction servers for the *in-silico* characterisation (Table 1). BLASTp and protBLAST servers were utilized for the sequence alignment and similarity searches [18,19]. Multiple sequence alignment of the protein with the homologous proteins were performed with the MUSCLE and visualised using the BoxShade server [20].

## Physicochemical characterisation

Physical and chemical parameters such as molecular weight, theoretical pI, amino acid composition, atomic composition, extinction coefficient, estimated half-life, instability index, aliphatic index, and grand average of hydropathicity predictions were performed using Expasys' ProtParam tool [21].

# Subcellular localisation analysis

Different prediction tools such as SignalP [22], SecretomeP [23], Psortb [24], PSL pred [25], Cello [26], SOSUIGramN [27], MetaLocGramN [28], TMHMM [8], HMMTOP [9] and CCTOP [10] were used for the topology prediction.

# Motif, domain, fold, coil, family and superfamily identification

Protein motif search was carried out using Motif (Genome Net) server [29]. Pfam and SuperFamily database searches were done to assign the proteins' evolutionary relationships. Protein folding pattern recognition were carried out using PFP-FunD SeqE server (14). For the detection of coiled-coil conformation within the protein, the COILS server was employed [30]. Protein sequence analysis and classification serverInterPro was employed for the functional analysis of the protein [15]. And STRING 10.0 search was carried out for the identification of possible functional interaction network of the protein [31].

# Virulent factor identification and vaccine candidate prediction

BTX pred toxin prediction, based on amino acid or dipeptide composition through a support vector machine (SVM) module was used for the prediction of the possibility of protein as a toxin [32]. For virulent factor analysis and annotation, VICM pred and MP3 (integrated SVM-HHM approach) servers were employed [33,34]. Antigen prediction was employed through VaxiJen server [16]. And BC pred and IEDB Parker hydrophilicity predictions were used for the identification of antigenic B-cell epitopes of the protein [35,36]. In addition a BLAST analysis against the human genome was performed for the detection of the autoimmune nature of the protein.

# Secondary structure analysis

PSIPRED and SOPMA servers were used for the prediction of the proteins' secondary structure [37,38].

#### Results

#### Sequence and similarity information

The proteins' BLAST searches revealed the similarity with few proteins belong to the other serovars of pathogenic Leptospira interrogans, which was as shown in Table 2. And Figure 1 depicts the multiple sequence alignment of the protein with the homologous proteins. At the same time no similarity was detected against the nonpathogenic Leptospira biflexa proteome.

## **Physicochemical features**

The protein consist of 722 amino acids, among the most abundant were Leu and Lys (69) followed by Glu and Ser (64), Asn (53), Ile (48), Gly and Val (40), Asp, Phe and Thr (36), Ala and Arg (31), Pro (30), Tyr (25), Gln (24), His and Met (10), Trp (5) and Cys (1). The calculated molecular weight was 82145.1Da and theoretical pI was 7.17. Total number of positively charged residues (Arg+Lys) and the total number of negatively charged residues (Asp+Glu) was found

to be 100. The computed instability index, aliphatic index and grand average of hydropathicity (GRAVY) were 28.69, 83.56, and -0.572 respectively. Extinction coefficient predicted at 280nm was 64750. Protein half -life computed was found to be 30 hours in mammalian reticulocytes (*in vitro*), > 20 hours and >10 hours in yeast and E. coli (*in vivo*) respectively. And the molecular formula of protein was identified as C3674H5808N986O1125S11.

#### Subcellular localisation nature

Subcellular localisation analysis results presented in Table 3, displayed the proteins' extracellular localisation nature. The graphical representation of SignalP and TMHMM prediction results were displayed in Figure 2 & 3.

Motif, domain, fold, coil, family and superfamily and functional details

Motif search by Motif server (genome net) identified a galactokinase against NCBI cdd, but no homologs in Prosite or Pfam databases. Domain search on Pfam was negative. Moreover, there was no significant hit against Superfamily search. Fold pattern recognition by PFP-FunDSeqE tool revealed the presence of an 'immunoglobulinlike' fold within the protein sequence. And COILS server revealed the

presence of a coiled-coil motif (Figure 4). There was no functional relation information by InterPro functional analysis. The predicted protein interaction network through the STRING analysis as shown in Figure 5. And the identified functional partners with scores were; LA\_1017 (0.859), LA\_1015 (0.859), LA\_1014 (0.469), LA\_1019 (0.445), and LA\_1018 (0.445).

# Virulent factor identification and vaccine candidate prediction

The protein possibility as an exotoxin was predicted through a support vector machines (SVM) module based on amino acid sequences with 96% accuracy through BTX pred server. VICM pred analysis classified the protein as metabolism related molecule through a support vector machine based pipeline. AndVaxiJen prediction presented the protein as an antigen with a significant score 0.6185 (threshold 0.4). The explored potential linear B-cell epitopes of the protein were listed in Table 4. And Figure 6 illustrates the antigenic epitopes of the protein identified through the Parker Hydrophilicity method. Moreover, no similarity result was showed against human proteome BLAST.

#### Secondary structure

The SOPMA secondary structure prediction server analysis revealed the proportions of alpha helix, beta turn, extended strand and the random coil of protein as 21.19%, 10.80%, 28.12%, and 39.89% respectively. Figure 7 illustrates the secondary structure alignments of the protein, identified through the PSI PRED server.

# **Discussion**

The sequence information collected from the NCBI database revealed the protein as "uncharacterised" protein. Further sequence alignment and comparison using the BLASTp and protBLAST searches showed the similarity to only a few proteins belongs to the pathogenic candidate Leptospira interrogans. Furthermore, the absence of sequence similarity to the non-pathogenic candidate Leptospira biflexa can be implicated to the virulent nature of the protein. ProtParam physicochemical characterisation classified the protein as stable with the instability index 28.69 [39], which is an estimation of stability of protein in a test tube [4]. The identified high aliphatic index data gives an indication of proteins' stability over a wide temperature range, and extinction coefficient value correlates to the concentration of Cys, Trp, and Tyr. Moreover, the negative GRAVY (-0.572) indicates the hydrophilic and the soluble nature of the protein [40,41].

The proteins' signal peptide and cleavage site prediction (between 21and 22 positions) by SignalP analysis gives an indication of the

secretory nature of the protein. Further TMHMM, HMMTOP, CCTOP results strengthen this data by avoiding the possibility of trans membrane helix presence within the protein sequence. The SignalP and SecretomeP results point to the secretion of protein though classical secretory pathways. Besides other subcellular localisation tools such as Cello, Psortb, SoSuiGramN, and MetaLocGramN were also explained the subcellular localisation of protein as extracellular. Which may give insights into the functional relations of the protein.

In case of this protein no domain features and family relationships could be predicted with confidence, which relates to the unknown nature of the protein. Concurrently the analysis showed the presence of an immunoglobulin-like fold and coiled-coil motif. Immunoglobulinlike (Ig-like) fold proteins have a role in immune functions. They can participate in interactions with other immunoglobulin-like domains via their beta sheets (a pair of Greek-key beta barrel) [42]. So protein fold recognition may allow the understanding of protein structure and function; based on the fact that proteins with different sequence information can adopt similar structures and similar functions [43]. Likewise, coiled-coil motifs are structural units formed from the supercoiling of alpha helices, with implications in biological functions such as regulation of gene expression [44]. Facilitates the protein-protein interactions by cementing the interfaces between the proteins. Its predictions are helpful for the identification of protein domain boundaries and potential protein interacting partners [45].

Protein-protein interaction identification helps to imply the functions of the proteins based on their interacting network [4]. The SRING analysis showed the interactions of this protein with other Leptospiral proteins such as LA\_1017, LA\_1015, LA\_1014, LA\_1019, and LA\_1018. Among, LA\_1017 is a TPR repeat containing protein. The TPR repeat motifs mediate the protein-protein interactions and modulate the assembly of multi protein complexes. Thus the interaction of the protein with these interacting partners and involvements in their functions are remained to be studied.

Toxin prediction analysis revealed the possibility of protein as an exotoxin. Exotoxins are soluble proteins secreted by the bacteria, diffuse through the organism to act at distant places from the site of infection. Exotoxins include neurotoxins, enterotoxins and cytotoxins and are involved in various biological functions [32]. As an exotoxin, this proteins' ability of binding to specific receptors on the cell's plasma membrane and pore formation remains to be studied, which may open up extra dimensions in leptospirosis research. Furthermore, the virulence factor analysis presented the protein as a metabolism related molecule. Protein possibility as an antigenic candidate from the result of VaxiJen and less chance of autoimmune induction gives an indication of this proteins' potential for the consideration as a vaccine candidate. In addition, the revealed B-cell epitopes of the protein are antigenic regions with the potential of peptide driven diagnostic and vaccine candidate efficiency. Even though in vitro confirmation of the annotated virulent characteristics are mandatory for the full characterisation of the protein.

The presented *in-silico* characterisation data gives an indication of the proteins' significance in the biology of Leptospira. The secondary structure information may give insights into the higher order structure and functional annotation of the protein. And the revealed extracellular nature points to the possibility of this protein

#### **Austin Publishing Group**

as a valuable diagnostic target. As extracellular proteins are readily exposed to the host immune system, this proteins' involvement in the immuno-pathogenesis of Leptospirosis is to be discovered. Moreover, the development of diagnostic assays targeting these protein or antigenic peptides may lead to the early diagnosis of Leptospirosis.

# Conclusion

Identification and characterisation of new virulent molecules will strengthen basic knowledge on Leptospirosis. The *in-silico* characterised hypothetical protein LA\_1016 is an unknown protein with less similarity to existing characterised or annotated proteins. And the proteins' revealed characteristics such as extracellular nature, coiled-coil motif presence, immunoglobulin-like fold presence, toxic possibility and antigenic nature emphasise the significance of this protein. The possibility of this protein as a potential vaccine candidate and diagnostic target also could be considered. Further in-vitro confirmation of the annotated characteristics may lead to the identification of a novel protein, having an impact in the pathogenesis of Leptospirosis. So extended research has to be carried

out to experimentally validate these possibilities and to find out the proteins' role in the Leptospiral biology.
